

3-tier architecture for Zomato application.

Here, this login is responsible for authenticating users before allowing access to the system.

Frontend - collects user's credentials.

Middleware - Validates the input and applies authentication logic

Backend - stores user details & verifies the credentials match or no

2) Customer side

This side allows the users to browse, select and order items.

Frontend - displays restaurants menus and cart options.

Middleware - processes user actions such as searching, filtering and placing orders.

Backend - stores restaurant details, menu items and order information.

When a customer places a order, the request is processed by the server and stored in the database, and the response is sent back to the user.

3) Restaurant side:

This enables the restaurant owners to manage their services and orders

Frontend - provides dashboard to add remove restaurants, update menu and view orders

Middleware - accepting or rejecting orders

Backend - stores restaurant profiles, names & order records

This ensures that restaurants can efficiently manage and operate in real time.

4) payment side:

This allows to handle secure transaction processing
 Frontend - allows users to enter payment details.

Middleware - Validates the request and communicates with external payment services.

Backend - records transaction details and payment status.

if successful - payment confirmation is shown.

if failed - error message is displayed
