

3 Tier Architecture of Zomato Application

- * The first tier is the presentation layer, which includes mobile App and web interface where users browse restaurants, select food items, add them to cart and proceed to checkout.
- * This layer focuses on user interaction and provides interface for ordering and payment.
- * The second tier is application layer. It acts as bridge between front-end and backend. This handles authentication, order processing and integrates with payment gateways.
- * It also handles business logic such as calculating prices, applying discounts and sends notification to users and restaurants.
- * The third tier is datalayer. This stores all critical information that includes user details, restaurant menu, order details and payment records.
- * When a user places an order, the middleware verifies login, processes the order and connects to payment service. Once payment is confirmed, it updates order status and notifies restaurant to prepare the food.
- * The user receives confirmation and tracking updates. This ensures smooth, secure and scalable operations from order placement to successful checkout.
