

Zomato Application: -

① Step 1: - Login to Zomato http request ①

First, If you are freshly using Zomato the user should create account and login to application. For the further activities. The Front-End sends the http request to server. server triggers the user login check and the do authorization and authentication. Then server check the database and the required details/data is displayed.

② Step 2: - After login Open Zomato website / App.

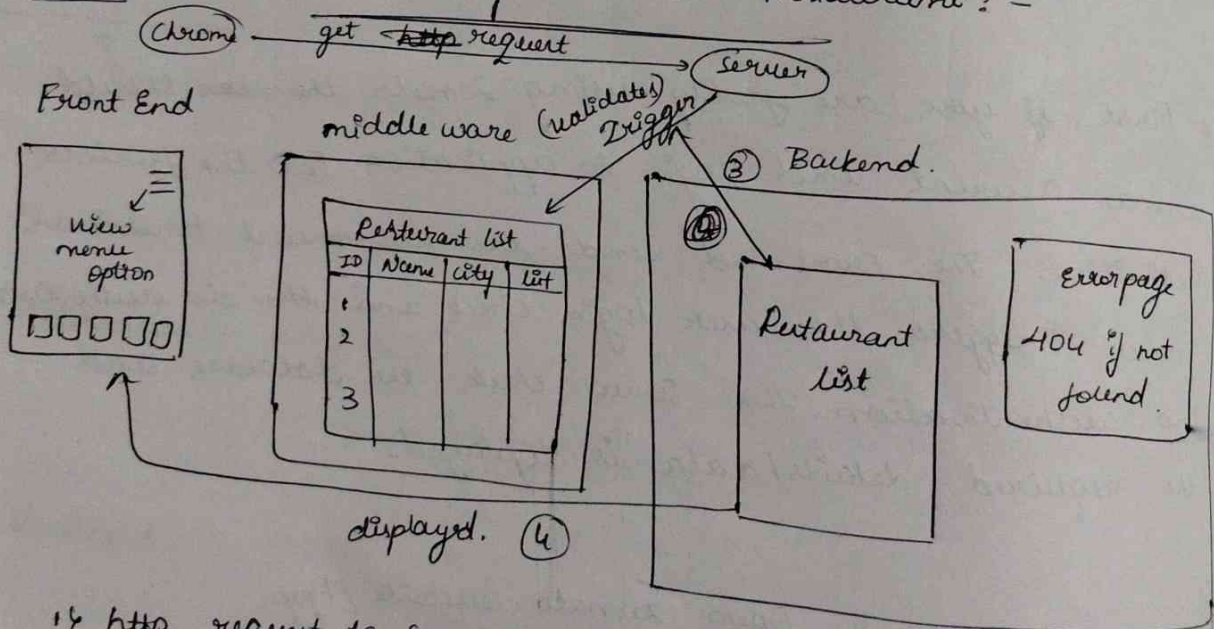

After login the Homepage of Zomato is displayed on Frontend.

Again,

- Http request sent to Server
- Server Triggers the middleware. checks if ~~city~~ restaurants are only of Bangalore. and sort it.
- And then fetch the restaurant list from Backend.
- Again the list is sent to Server.
- And response is displayed on screen.

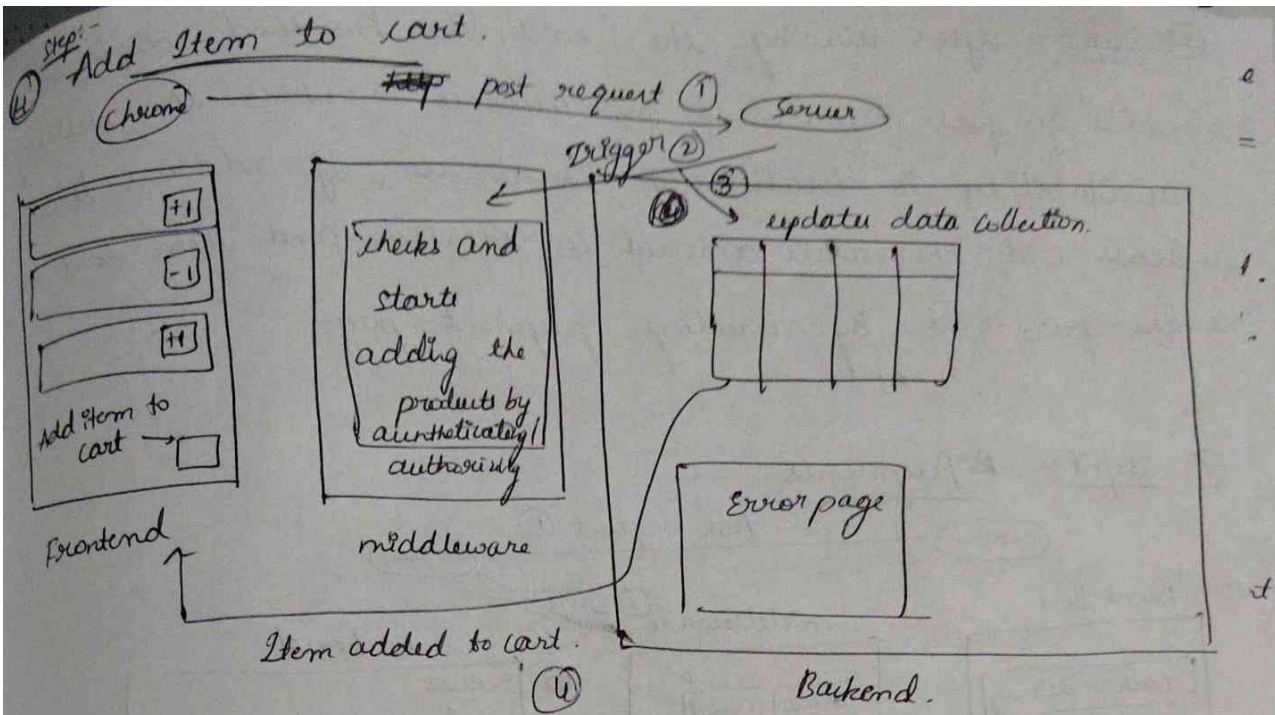

③

Step 3:- View menu of Selected Restaurant:-

1. http request to Server.
2. validates the restaurant ID and fetches menu from Database.
3. menu collection.
4. Response to request sent to Server.
5. Displayed on screen.

④

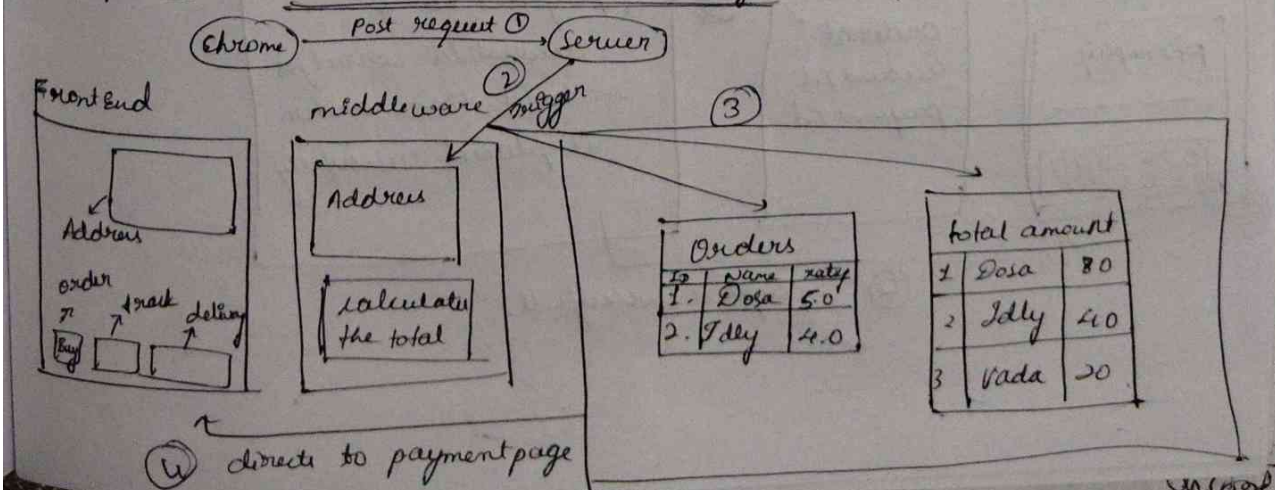

user start selecting the dishes / food and it starts to add to the cart. This request sent to server and server will triggers by checking the requested food available @ not in the data. once done again the collection of list is updated and returns cart count.

⑤ Step 5: - View Cart.

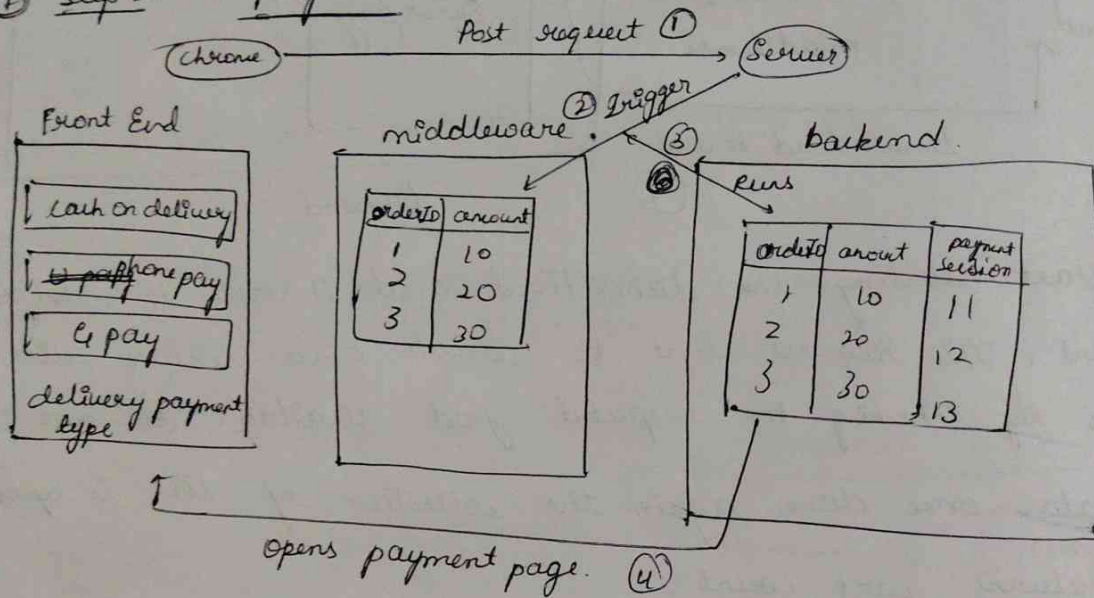

Front-end ⇒ view cart option, by sending the get-request to server.
 middleware ⇒ Fetches cart items and calculate total.
 Backend ⇒ Returns the updated cart data.

⑥ Step 6: - order & Address / delivery checking.

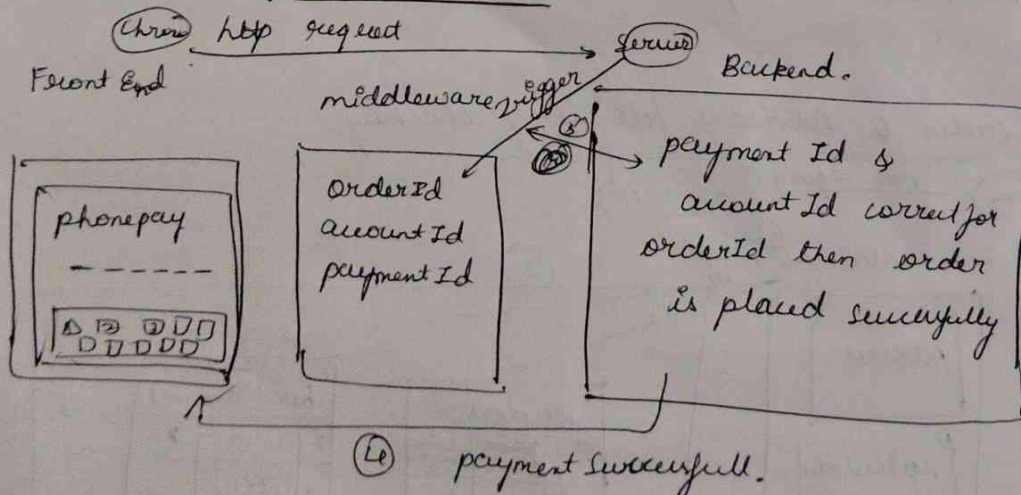

⑦ Step After viewing the cart. The Frontend displayed will go for my orders (or) Address to check the delivery availability to location. (or) Items as. If address have access and the total amount is counted and then sent to the front-end. By directing payment page.

⑦ Step 7:- Payments

Frontend sends post request to server and server authorize/authenticate the orderId and amount and then fetch the payment sessionID to server and displays back to Frontend.

⑧ Step:- payment success/info:-

After choosing type of payment the user need to enter the account pin to unlock the amount from bank, and in ~~middle ware~~ it checks if the

* In middle ware it checks if the OrderId and the paymentId. Also ^{whether} ~~whether~~ the accountId is in the specific Bank @ not.

* The fetches the detail from the Backend and Sends it to Server.

* Through which displays ~~the~~ on the frontend that payment done successfully.
